

# Homework 4

Due: December 1<sup>st</sup>

## Activation Record

Suppose we are using the following frame structure:

The register r1-r3 is caller-save and r4-r6 is callee-save, and no argument will be passed by any register. Besides, all callee-save registers used in a function will be pushed onto stack before it executes. Consider the execution of program() in the following code. Please complete the activation records when the function fun() is just about to finish:

### NOTE:

1. The registers and locals used in each function are annotated in their declaration.
2. You should indicate which addresses the static links point to by drawing arrows.

```

function program() : int =
  /* INFO of function program
  used registers: non
  spilled variables: retVal
  return address: P    */
  let
    var retVal := 0

    function foo(a:int, b:int) =
      /* INFO of function foo
      used registers: r1, r2, r4
      spilled variables: non
      return address: A    */
      let
        function bar(c:int) =
          /* INFO of function bar
          used registers: r2, r4, r6
          spilled variables: ret
          return address: C    */
          let
            var ret := 0;
            in ret := fun(a, b, c);
            print(ret)
          end

          /* body of function foo */
          in bar(5);
        end

      /* body of function program */
      in foo(3, 4);    retVal
    end
  end

function fun(d:int, e:int, f:int) : int =
  /* INFO of function fun
  used registers: r1, r3, r5
  spilled variables: output
  return address: B    */
  let
    var output := 0
    in if d > 0 then output := e - f
    else output := f - e ;
    output

  /* body of function program */
  in foo(3, 4);    retVal
end

```
